REFERENCE REPLY: LBNL Proposal BG 99-210 (00)  
Response to CALFED Bay-Delta Program 1999 Proposal Solicitation

Enclosed for your consideration is an original and nine (9) copies of the subject proposal along with electronic copy of text and tables as requested. This proposal is submitted on behalf of the Ernest Orlando Lawrence Berkeley National Laboratory (LBNL):

Title: Real-Time Sensors for Mercuric and Selenate Ions Utilizing Templated Polymer Technology

Principal Investigator: Richard H. Fish, PhD.

Total Amount Requested: \$793, 871.00

Period Requested: 2 Years

Type of Request: New

LBNL is operated by The Regents of the University of California for the Department of Energy (DOE) under prime contract DE-AC03-76SF00098 and all work is conducted under the terms of that contract and subject to the approval of DOE. This proposal will be submitted to DOE for approval.

Please note that we have had discussions this week with Ms. Jo Turner and Ms. Nan Yoder of CALFED with respect to determining the appropriate contract terms and conditions to be utilized if we are favored with an award under this program. It is our understanding that the applicable terms and conditions will be determined by the source of funds used to fund the specific project. Specifically, Ms. Turner and Ms. Yoder confirmed the following guidelines in determining the appropriate terms and conditions:

Page Two  
CALFED Bay-Delta Program Office  
April 15, 1999

FEDERAL FUNDS: If CALFED makes an award derived from federal funds, a federal interagency agreement would be the appropriate contractual vehicle used for performing the work at LBNL. The agreement would be between the federal sponsor and DOE. We can provide additional guidance if an award is contemplated. It should be noted that such agreement must include the following language:

"This agreement is entered into pursuant to the Authority of the Economy Act of 1932, as amended (31 U.S.C. 1535), and adheres to Federal Acquisition Regulation (FAR) 6.002 and other applicable Federal Laws and Regulations. To the best of our knowledge, the work requested will not place the DOE and its contractor in direct competition with the private sector."

STATE OF CALIFORNIA FUNDS: If CALFED'S funds for an award are derived from California state funds, Ms. Yoder expressed an interest in reviewing and possibly utilizing the master terms and conditions, or a variation thereof, currently being finalized between DOE and the California Energy Commission (CEC) for several CEC awards to LBNL. It was agreed that LBNL would provide a copy of the final CEC/LBNL agreement for CALFED's review at the time of a CALFED award to LBNL. It should be noted that the proposed CEC/LBNL agreement has been in negotiations over an extended period of time and is being reviewed by the California General Services Administration for their final approval.

As soon as a funding decision is made, please contact the undersigned wherein we will be able to mutually determine the appropriate contracting mechanism.

In addition, please note that LBNL intends to award a two-year subcontract to John Hopkins University (Applied Physics Laboratory) to support the efforts of LBNL's Dr. Richard Fish, at a cost of \$199,691.00 (see enclosed budgets).

If you have any questions regarding this submission, please feel free to call me on (510) 486-7391 or Facsimile No. (510) 486-4386.

Sincerely,

Richard W. Wilson  
Contracting Officer

## Executive Summary

Real-time management of west-side San Joaquin selenium drainage and management of Sacramento Basin mercury discharges are specified goals of the CALFED Water Quality Program. A demonstration of the capabilities and benefits of real-time salinity management by the SJRMP Water Quality Subcommittee has received funding by CALFED. Salinity can be measured in real-time through the real-time forecasting of the selenium (selenate,  $\text{SeO}_4^{3-}$ ) concentrations. Therefore, water quality cannot be performed with the requisite degree of accuracy for compliance purposes without the deployment of a continuously recording selenium sensor device. In the Grassland Bypass Project, neither electrical conductivity or flow are adequately correlated with selenium concentrations to be useful in selenium load forecasting. In the case of mercury mine discharge management from sources in Cache Creek, lack of a real-time sensor for continual mercury ( $\text{Hg}^{2+}$  [or  $\text{CH}_3\text{Hg}^+$ ]) analysis compromises the development and implementation of the Total Mass Daily Load (TMDL) program actions (the Cache Creek Hg Group was just funded by CALFED for this and other ecological studies), specified amongst the CALFED water quality actions. The project's primary benefit is to increase the frequency of meeting San Joaquin and Sacramento River water quality objectives for  $\text{SeO}_4^{3-}$  and  $\text{Hg}^{2+}$  ion concentrations.

Thus, this proposed project is focused on developing robust, real-time, selective sensors for mercury ( $\text{Hg}^{2+}$ ) monitoring in Cache Creek in the Sacramento River Basin and, as well, selenium (selenate,  $\text{SeO}_4^{3-}$ ) monitoring in the San Joaquin River and its west-side tributaries. Research, development, and deployment phases of the proposed two year project involves the following tasks for application of state-of-the-art metal/metalloid ion templated polymer technology, previously used to develop a real-time, selective sensor for lead ions ( $\text{Pb}^{2+}$ ), to novel, templated polymer sensors for  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  and includes: (a) Synthesis of the  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  monomer complexes containing designer ligands for optical and electrochemical detection; (b) Polymerization of these templated monomer complexes, to create several novel, templated polymers selective to reintroduced  $\text{Hg}^{2+}$  or  $\text{SeO}_4^{3-}$  ions; (c) Fabrication of fiber optic or electrode probes for field deployment of real-time, selective sensors for  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  ions; (d) Determination of the selectivity and analytical sensitivity parameters (parts per trillion range), and; (e) field deployment of these real-time, selective sensor devices for long-term  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  ion monitoring at environmental sites of interest. See Scheme 1, for an explanation of the imprinted polymer concept.

### Templated Polymer Technique

Scheme 1

What is clearly evident is that without real-time sensors for  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  ions, or for that matter any toxic metal ion of environmental interest, no real-time management for acute toxicity monitoring to mitigate the effects of the high concentrations of these metal ions will be viable. The primary stressor addressed by the program is contaminants entering the lower San Joaquin River and Cache Creek, which empties into the Sacramento River. The primary ecosystem and water quality benefits of sensor development will include: (a) allow real-time management of selenium discharges into the San Joaquin River and (b) allow improved management of mercury loads from mines in the Cache Creek watershed (\*see attached letters from constituency groups supporting this proposal and the concept of real-time sensors for real-time ecosystem management).

Secondary benefits from selective  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  sensor development are a likely reduction in the number and/or magnitude of violations of the EPA selenium concentration objectives for the San Joaquin River downstream of the Merced River and of EPA mercury objectives in Cache Creek. Species and species groups benefiting from reduced selenium and mercury concentrations besides chinook salmon and steelhead trout, are delta smelt, longfin smelt, splittail, white and green sturgeon, striped bass, marine/estuarine fishes and large invertebrates, and Bay-Delta aquatic foodweb organisms.

## **Project Description**

### **Project Description and Approach**

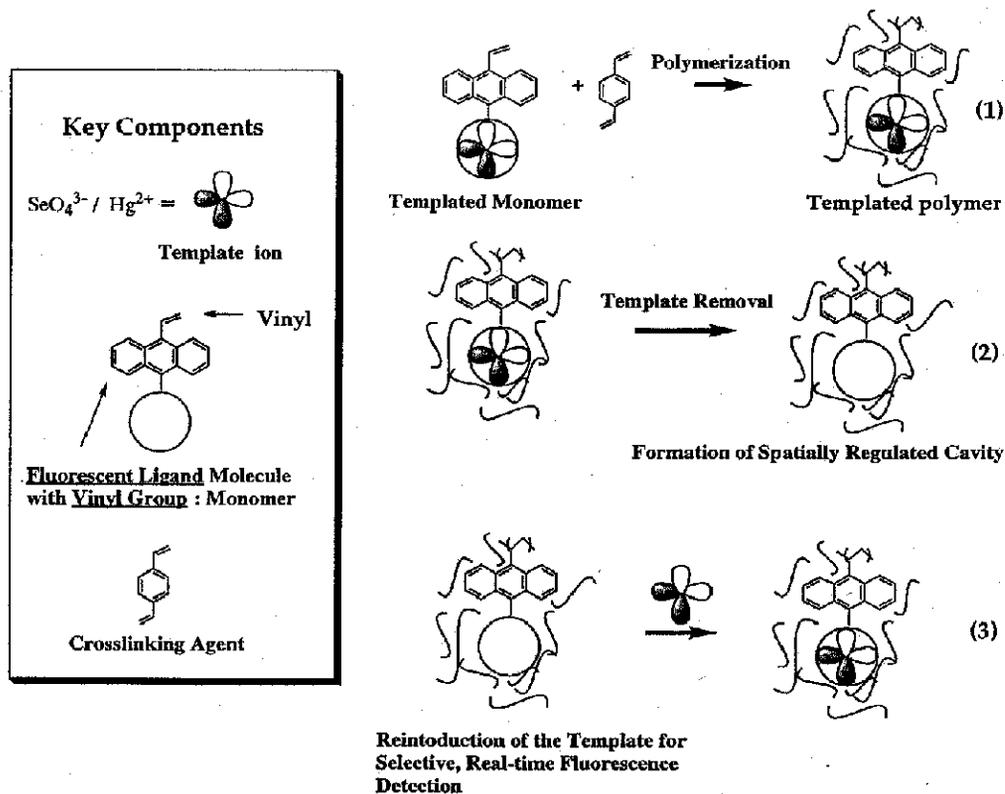

The goal of the proposed project is to develop real-time, selective sensors for mercury ( $\text{Hg}^{2+}$ ) monitoring in Cache Creek in the Sacramento River Basin and selenium (selenate,  $\text{SeO}_4^{3-}$ ) monitoring in the San Joaquin River and its west-side tributaries. Research, development, and deployment phases of the proposed two year project involve the following tasks for application of state-of-the-art metal/metalloid ion templated polymer technology, previously used to develop a real-time, selective sensor for lead ions ( $\text{Pb}^{2+}$ ), to new, templated polymer sensors for  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  and includes: (a) Synthesis of  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  monomer complexes containing designer ligands for optical or electrochemical detection; (b) Polymerization of these templated monomer complexes, to create several new, templated polymers selective to reintroduced  $\text{SeO}_4^{3-}$  or  $\text{Hg}^{2+}$  ions; (c) Fabrication of fiber optic/electrode probes for field deployment of real-time, selective sensors for  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  ions and; (d) Determination of the selectivity and analytical sensitivity parameters and; (e) field deployment of these real-time, selective sensor devices for long-term  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  ion monitoring at designated environmental sites.

### **Application of Templated Polymer Technology.**

The concept of selective, metal/metalloid ion templated polymers has been studied by Fish and co-workers ( $\text{Hg}^{2+}$  and copper ( $\text{Cu}^{2+}$ ) amongst others (2), while Murray and co-workers have designed, developed, and deployed instruments for field optical and electrochemical sensing of metal ions, such as lead ( $\text{Pb}^{2+}$ ) and uranium ( $\text{UO}_2^{2+}$ ), as well as organic compounds, such as the hydrolysis product of the nerve agent, soman (3). The basic templated polymer premise (Figure 1) involves: (Cartoon 1) forming a imprinted/templated metal/metalloid ion-monomer complex followed by co-polymerization with a crosslinking agent, such as divinylbenzene, to form a templated metal/metalloid ion-polymeric ligand matrix (bulk materials). The ultimate goal (Cartoon 2) of the templated metal/metalloid ion-polymeric ligand complex, thus formed, is to remove the template ion by, for example, acid treatment, and the subsequent reintroduction (Cartoon 3) of the metal/metalloid ion used as the template allows repeated recognition, in a selective manner, when other ions compete with it for the same polymeric, spatially regulated ligand site. *Thus, selectivity for a specific metal/metalloid ion can be tailored by providing templated polymers with spatially regulated sites and complexing ligands so arranged as to match the charge, coordination number, coordination geometry, and ionic radius of the toxic metal /metalloid ions to be detected.*

Figure 1

Templated Polymer Technique

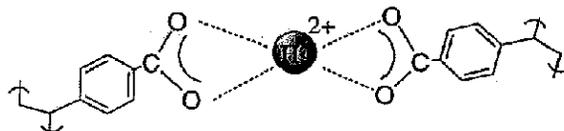

Many sensor parameters that are critical for performance; i.e., selectivity, sensitivity, and lack false positive responses, are not well developed and, apart from Murray's sensor devices, efforts to develop these metal ion sensors have not been successful for the following reasons:

1. **Low selectivity:** Competition with other metal ions that might bind to the ligand.
2. **Low sensitivity:** parts per million range, rather than the parts per trillion range
3. **False positive responses:** Other metal ions interfere by binding to the ligand site diminishing the concentration reading and misleading the analyst.

*More importantly, as far as we aware, no selenium sensor exists or has been developed for real-time environmental monitoring, while those available for mercury ions are not*

*selective, sensitive, reliable, nor portable. Clearly, new innovative approaches for metal/metalloid, real-time sensors are urgently needed by the environmental community.* **Synthesis of  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  Monomer Complexes and Polymerization Studies to Create Templated Bulk Polymers.**

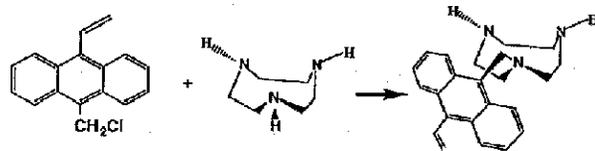

Murray et al. have constructed both a lead ( $\text{Pb}^{2+}$ ) electrode and a fiber optic device for real-time sensing of lead ( $\text{Pb}^{2+}$ ) ions in the 1-5 parts per trillion (ppt) range with the 4-vinylbenzoic acid- $\text{Pb}^{2+}$  complex.<sup>3a</sup> They have also environmentally tested the  $\text{Pb}^{2+}$  ion selective electrode device in rivers in Maryland. Thus, we wish to utilize this same approach for constructing electrode and fiber optic devices for mercury ( $\text{Hg}^{2+}$ ) ion real-time sensors, so that we can test this device the first year for selectivity and analytical sensitivity at the sites of interest. Initial studies will include fluorescent spectral analysis of the 4-vinylbenzoic acid- $\text{Hg}^{2+}$  complex, selectivity with other competing metal ions, and analytical sensitivity measurements (ppt range) to determine appropriate parameters for real-time analysis of  $\text{Hg}^{2+}$  ions at environmental sites of interest. Polymerization studies of the  $(4\text{-vinylbenzoic acid})_2\text{Hg}^{2+}$  complex, on an fiber optic or electrode surface will be followed by testing at environmental sites of interest.

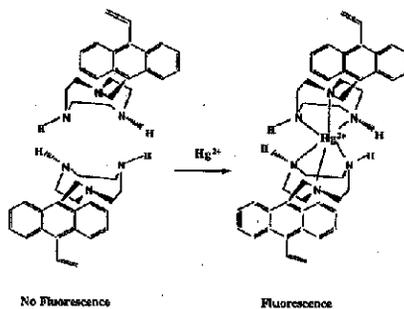

**Figure 2:** Mercury Selective, Templated Polymer for Real-Time Detection

In another method, that may provide a more selective and sensitive  $\text{Hg}^{2+}$  ion sensor, the following templated  $\text{Hg}^{2+}$ -monomer complex will be synthesized by the reaction shown below and its fluorescence spectral properties fully studied (Figure 3). The two new approaches will be used to develop highly selective and sensitive sensors for both  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  ions. The first approach entails the photo-induced electron transfer technique (PET), where the non-metal containing monomer (Figure 4) *does not provide fluorescence* due to a quench of this optical phenomena via the non-bonding electrons of the nitrogen atoms, but the  $\text{Hg}^{2+}$  complex *does fluoresce* when the nitrogen atom non-bonding electrons are bound to  $\text{Hg}^{2+}$ ; Figure 5 shows the same process with the templated polymer. Thus, high  $\text{Hg}^{2+}$  ion selectivity to this system, already shown by Fish et al.<sup>(2d)</sup> for a somewhat similar non-fluorescent system, will expedite the  $\text{Hg}^{2+}$  ion optical

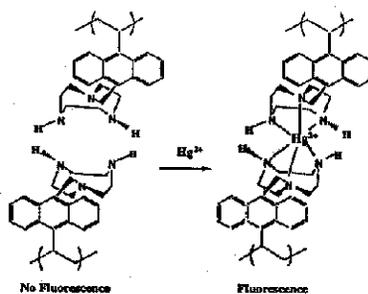

sensor development; a similar approach can be accomplished for  $\text{CH}_3\text{Hg}^+$  if there is interest from CALFED.

**Figure 3:** Synthesis of a Mercury Selective, Monomer Ligand, Non-Fluorescent by the PET process

**Figure 4:** Synthesis of a Fluorescent, Monomer-Mercury Complex

**Figure 5:** Demonstration of Quenched (PET) and the Enhanced Fluorescence Process with the  $\text{Hg}^{2+}$  Templated Polymer

The other technique for a  $\text{SeO}_4^{3-}$  sensor, used previously by Murray and co-workers for a Saran/Soman sensor (3a,b), utilizes a proposed europium ion-selenate complex that shifts the fluorescence spectrum to a unique wavelength for highly, selective

selenate detection and quantitation (Figure 6). Figure 7 clearly shows an example of a shifted fluorescence spectrum for selective lead ion ( $\text{Pb}^{2+}$ ) detection at 544 nm.

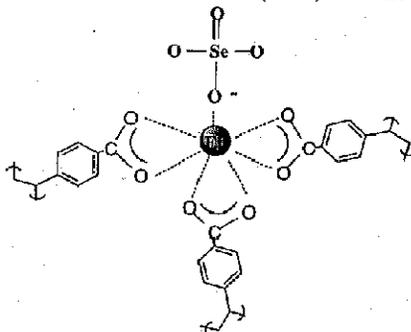

Figure 6: Europium-selenate polymer for selective  $\text{SeO}_4^{3-}$  detection via a fluorescent\_wavelength shift

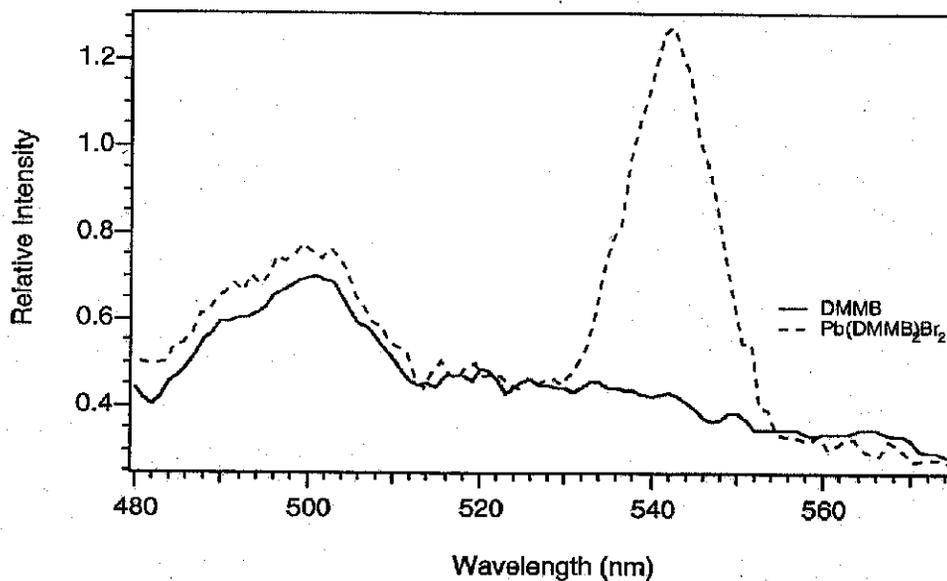

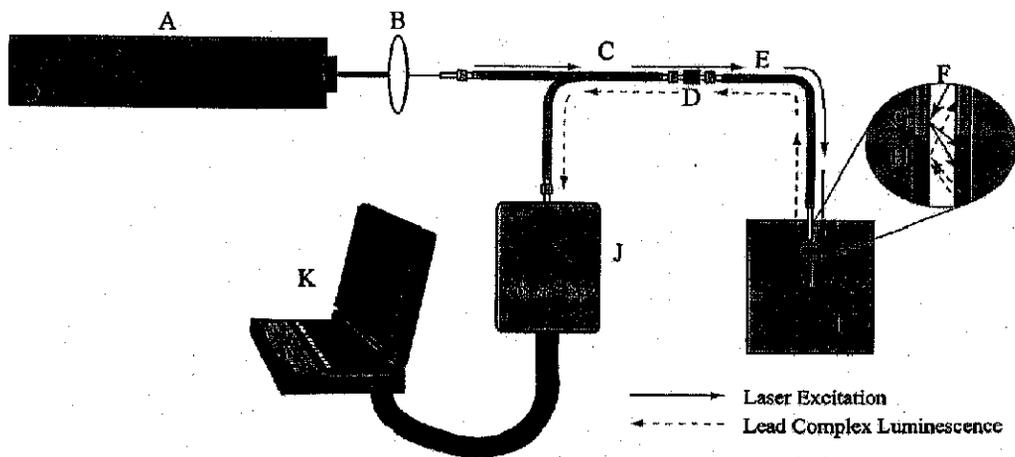

Figure 7. The spectra of the templated benzoic acid methyl ester ligand and its lead complex. Excitation with a 466.7 nm line of the argon-ion laser; detection of  $\text{Pb}^{2+}$  ions at ~ 544 nm.

### Fabrication of Fiber Optic Sensors.

As an example of how we will generate a sensor device, these  $\text{SeO}_4^{3-}$  and  $\text{Hg}^{2+}$  monomer complexes can be bound by *in situ* co-polymerization to a  $400\ \mu\text{m}$  optical fiber surface. The luminescence spectrum of the polymer-coated optical fibers should show the same characteristic bands as the precursor templated  $\text{SeO}_4^{3-}$  and  $\text{Hg}^{2+}$  ion complexes. Prior to coating with the templated polymer, the fiber was washed with ethanol and distilled water. Varying amounts of the complex are then mixed with styrene, combined with a crosslinking agent divinylbenzene (DVB), and subjected to polymerization with constant mixing in the ultrasonicator. Azobisisobutyronitrile (AIBN) was used as an initiator in the amount of roughly 1 mole %. Polymerization will be carried out in a sealed vial with a inert ( $\text{N}_2$ ) atmosphere to avoid the quenching of the free radicals by oxygen. Polymerization will be allowed to proceed until the content acquired a viscous/sticky consistency, at which moment the seal is broken and the optical fiber dip-coated with the polymer. Coated fibers will subsequently be cured overnight with UV light. The polymer coat is then swollen in the water/methanol solution and treated with EDTA or dilute acid to release the templates,  $\text{SeO}_4^{3-}$  or  $\text{Hg}^{2+}$ , coordinated by the polymerized ligands. The fluorometric probe will then be attached to the common trunk of the fiber. The polymer coated onto the tapered end of the fiber will be excited evanescently (light activated) and the resulting metal-ligand fluorescence will be collected into the same fiber, transmitted back to the bifurcation (fiber) and registered through the other leg using a portable fiber-optic spectrophotometer and portable lap-top computer (Figure 8).

#### **Ecological/Biological Benefits**

The primary stressor addressed by the program is contaminants entering the lower San Joaquin River and Cache Creek, which empties into the Sacramento River. The primary ecosystem and water quality benefits of sensor development are to: (a) allow real-time management of selenium discharges into the San Joaquin River and (b) allow improved management of mercury loads from mines in the Cache Creek watershed.

Secondary benefits from sensor development are a likely reduction in the number and/or magnitude of violations of the EPA selenium concentration objectives for the San Joaquin River downstream of the Merced River and of EPA mercury objectives in Cache Creek. Species and species groups benefiting from reduced selenium concentrations besides chinook salmon and steelhead trout, are delta smelt, longfin smelt, splittail, white and green sturgeon, striped bass, marine/estuarine fishes and large invertebrates, and Bay-Delta aquatic foodweb organisms.

During the final year of the research and development phase of the proposed project the research team will upgrade key real-time SJR water quality monitoring stations with the prototype selenium sensor device and deploy the mercury sensor device at monitoring locations downstream from the most important mercury discharge or source points. This information provided by the final year deployment of the prototype sensor devices can be used to assess the impact of other management practices that attempt to reduce the toxic metal ion pollutant load into the lower SJR and Bay-Delta. Species and species groups benefiting from reductions in contaminants entering the Bay-Delta are delta smelt, longfin smelt, splittail, white and green sturgeon, striped bass, resident fish species, marine/estuarine fishes and large invertebrates, Bay-Delta aquatic foodweb organisms, and waterfowl.

Non-ecological CALFED objectives addressed by the program include improving Bay-Delta water quality for drinking water, industrial, and recreational beneficial uses. The program will facilitate the control and timing of agricultural and mining drainage to coincide with periods when dilution flow is sufficient to achieve CALFED water quality concentrations. The discharge into the SJR of agricultural drainage that is high in selenium is one of the most serious contaminant problem in the Bay-Delta. Selenium (selenate,  $\text{SeO}_4^{3-}$ ) has caused reproductive failure in sensitive fish species and developmental deformities in waterfowl and shorebirds, because of its ability to bioaccumulate within food

chains in plant and animal tissue to levels that can be toxic to higher trophic organisms. Finally, the program will be managed to dovetail with CALFED's Water Quality Program, the geographic scope of which is limited to the legally defined Delta.

#### **Background and Biological/Technical Justification**

Real-time management of west-side San Joaquin selenium drainage and management of Sacramento Basin mercury discharges are specified goals of the CALFED Water Quality Program. A demonstration of the capabilities and benefits of real-time salinity management by the SJRMP's Water Quality Subcommittee has received funding by CALFED. Salinity can be measured in real-time through the real-time forecasting of selenium water quality cannot be performed with the requisite degree of accuracy for compliance purposes without the deployment of a continuously recording selenium sensor device. In the Grassland Bypass Project neither electrical conductivity or flow are adequately correlated with selenium concentrations to be useful in selenium load forecasting. In the case of mercury mine discharge management from sources in Cache Creek, lack of a continuously recording mercury sensor compromises the development and implementation of the Total Mass Daily Load (TMDL) program actions, specified amongst the CALFED water quality actions. The project's primary benefit is to increase the frequency of meeting San Joaquin and Sacramento River water quality objectives for selenium and mercury ion concentrations.

#### **Deployment of Real-Time Selenate and Mercuric Ion Sensors.**

Real-time sensor devices for mercury ( $\text{Hg}^{2+}$ , sensitivity in the ppt range) and selenium ( $\text{SeO}_4^{3-}$ , sensitivity in the ppt range) ions will be installed at existing monitoring sites currently maintained by the CRWQCB, USGS, and local agencies. The sensor devices will be designed to give a 0-5V DC output so as to be compatible with current datalogging systems such as the Campbell CR-10 used by the USGS or the HANDAR 2000 used by the Department of Water Resources. The sensor devices can be used for long-term monitoring, but will need to be EDTA or acid washed to remove the just determined metal ion concentration after each experiment. This procedure can be easily and safely done on-site.

#### **Location and/or Geographic Boundaries of Project**

The geographic area encompassed by the program is the lower San Joaquin River basin, including west-side tributaries, in the following counties: Stanislaus, Merced, Modesto, San Joaquin, Tuolumne; and Cache Creek in Yolo County.

### **Justification for Project and Funding by CALFED**

Real-time management of west-side San Joaquin selenium drainage, and management of Sacramento Basin mercury discharges are specified goals of the CALFED Water Quality Program. Real-time forecasting of selenium water quality cannot be performed with the requisite degree of accuracy for compliance purposes *without the deployment of a real-time, selective selenium ( $\text{SeO}_4^{3-}$ ) and mercury ( $\text{Hg}^{2+}$ ) ion sensors*. In the Grassland Bypass Project, neither electrical conductivity measurements nor flow measurements are adequately correlated with selenium ( $\text{SeO}_4^{3-}$ ) concentrations to be useful in selenium load forecasting. In the case of mercury mine discharge management from sources in Cache Creek, lack of a real-time mercury ( $\text{Hg}^{2+}$ ) ion sensor compromises the development and implementation of the Total Mass Daily Load (TMDL) program actions, specified amongst the CALFED water quality actions. The project's primary benefit is to increase the frequency of meeting San Joaquin and Sacramento River water quality objectives for selenium ( $\text{SeO}_4^{3-}$ ) and mercury ( $\text{Hg}^{2+}$ ) ion concentrations. More importantly, there are no available commercial real-time, selective sensors for either selenium ( $\text{SeO}_4^{3-}$ ) or mercury ( $\text{Hg}^{2+}$ ), and thus a global environmental need for these type of sensor devices would position the CALFED program as the leading agency in their development, fabrication, and deployment. Thus, these templated polymer sensors are: (1) Timely need for these devices; (2) more economical than sampling techniques and off-site analysis; (3) Action can taken immediately to address environmental problems; (4) acute toxicity events are known more quickly via logged concentrations of toxic metal ions at frequent intervals.

### **Monitoring and Data Evaluation**

The monitoring data gathered during field deployment of the selenate and mercuric ion sensor devices will be compared to field data collected by the CRWQCB and other agencies at key monitoring locations. Data comparisons will be published, to encourage technology transfer for the new templated polymer sensor technology where appropriate.

### **Program Support and Compatibility with CALFED Objectives**

The project is directly related to the recommended CALFED Water Quality Program actions to develop a real-time selenium water quality management system for the lower San Joaquin River, and to develop a TMDL for mercury load management to Cache Creek. The project goals have considerable support amongst the potential user community including the San Joaquin River Management Program (SRMP), the California Regional Water Quality Control Board (CRWQCB-CVR), the United States Bureau of Reclamation and local San Joaquin basin and Sacramento basin stakeholders.

### **Participants/Collaborators in Implementation:**

San Joaquin River Management Program (SJRMP); California Regional Water Quality Control Board, Central Valley Region (CRWQCB-CVR)

United States Bureau of Reclamation; Local SJR basin stakeholders (reservoir operators, water and drainage districts). The SJR Real Time Water Quality Monitoring Network Demonstration Project confirmed the technical feasibility of real time monitoring in the Lower SJR Basin. Successful implementation of this project will: Facilitate the control and timing of agricultural drainage to coincide with periods when dilution flow is sufficient to achieve CALFED water quality concentrations (CALFED Priority Action 1).

Support efforts of local watershed programs that improve water quality parameters of concern within the Delta tributary watersheds (CALFED Priority Action 21) by providing real time water quality data and forecasts to river stakeholders.

### **Scope and Tasks to Accomplish Project**

The scope of work encompassed by sensor research and development implementation requires funding for the following tasks:

**Task 1** Synthesis and characterization ( $^1\text{H}$  NMR, MS, Elemental analysis) of the monomer ligands, N-(9-vinylanthracenyl)TACN and 4-vinylbenzoic acid, and studies of their fluorescence spectra to ascertain a unique wavelength for each ligand or to observe a fluorescence quench known as the Photoinduced Electron Transfer Effect (6 months to 1 year at LBNL).

**Task 2** Synthesis and characterization (NMR, MS, elemental analysis) of the monomer N-(9-vinylanthracenyl)TACN-mercury ( $\text{Hg}^{2+}$ ) and bis(4-vinylbenzoic acid)- $\text{Hg}^{2+}$  monomer complexes and study of their fluorescence properties for specific wave-length determination for the sensor application. Synthesis and characterization of the monomer tris(4-vinylbenzoic acid)Eu- $\text{SeO}_4^{3-}$  complex and study its' fluorescence properties for specific wave-length determination for the selenium sensor application (first year, LBNL/JH-APL).

**Task 3** Bulk polymerization studies of the monomer N-(9-vinylanthracenyl)TACN-mercury ( $\text{Hg}^{2+}$ ) and bis(4-vinylbenzoic acid)- $\text{Hg}^{2+}$  complex, removal of the  $\text{Hg}^{2+}$  ion template with 6N hydrochloric acid treatment, and selectivity studies of the templated polymers with  $\text{Hg}^{2+}$  ions and other potential competing metal ions in the actual water samples that will be used for future real-time  $\text{Hg}^{2+}$  ion sensing. Similar studies with the monomer tris(4-vinylbenzoic acid)Eu- $\text{SeO}_4^{3-}$  complex will also be accomplished using the same protocol as described for  $\text{Hg}^{2+}$  ions (end of first year and second year, LBNL/JH-APL).

**Task 4** Polymerization of the monomers N-(9-vinylanthracenyl)TACN-mercury ( $\text{Hg}^{2+}$ ) complex, bis(4-vinylbenzoic acid)- $\text{Hg}^{2+}$ , and the tris(4-vinylbenzoic acid)Eu- $\text{SeO}_4^{3-}$  complex onto fiber optic and electrode probes for real-time sensors. Analytical data-selectivity (high for metal ion to be detected), and sensitivity parameters (ppt range) using the set-up described in Figure 8 (second year), JH-APL/LBNL).

**Task 5** Field studies with the portable laptop computer and fiber optic/electrode probe for the accurate, selective measurements of both  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  ions at the environmental sites of interest (first year [ $\text{Hg}^{2+}$ ] sensor and second year [ $\text{SeO}_4^{3-}$ ], LBNL/JH-APL).

\*\*See the Table below that we have constructed as the equivalent to the Hypothesis Testing Information for Real-time Sensor Development in a specific Task sequence. To reiterate, it is essential that all tasks are funded, since each task is critical for the next task to be accomplished.\*\*

Real-time Sensor Development in Sequence

| Sensor Objectives <sup>a</sup> |   |   |               |
|--------------------------------|---|---|---------------|
| Task 1                         | Synthesis of the monomer ligands selective for $\text{Hg}^{2+}$ and $\text{SeO}_4^{3-}$                       | High selectivity to metal ion of choice is critical for sensor development                                      | High Priority |
| Task 2                         | Synthesis of the monomer- $\text{Hg}^{2+}$ and $\text{SeO}_4^{3-}$ complex and fluorescence spectral analysis | Determination of the unique wave-length for specific detection of $\text{Hg}^{2+}$ or $\text{SeO}_4^{3-}$       | High Priority |
| Task 3                         | Bulk polymerization of $\text{Hg}^{2+}$ and $\text{SeO}_4^{3-}$ ; selectivity with the demetallated polymer   | Determination of the selectivity upon reintroduction of $\text{Hg}$ or $\text{Se}$ to the bulk polymer material | High Priority |
| Task 4                         | Polymerization of monomers to the fiber optic / electrode probes for sensitivity studies in the ppt range     | Fabricate sensor device for testing for the ppt sensitivity limits  | High Priority |
| Task 5                         | Field studies at the sites of interest described in the text  | Testing portable unit for long-term monitoring studies  | High Priority |

<sup>a</sup>It should be clear that for each metal ion sensor, the Task sequence, 1-5, has to be followed. Thus, in order to fabricate a real-time sensor, each Task must be accomplished in sequence.

**Schedule Milestones**

**First year:** Synthesis of  $\text{Hg}^{2+}$  and  $\text{SeO}_4^{3-}$  vinyl monomer complexes; selectivity to competing metal ions, sensitivity studies in the parts per trillion range (ppt), and polymerization studies. Start the fabrication of the devices, both optical and electrochemical for  $\text{Hg}^{2+}$  and/or  $\text{SeO}_4^{3-}$ , whichever is more important to the goals of CALFED.

**Second Year:** Fabrication of devices and testing the fiber optic and electrochemical sensors for analytical limits (parts per trillion), while initiating field tests.

MECHANICAL SERVICES GROUP + ENERGY CONVERSION

NO. 026

003

1-018638

### **Applicant Qualifications:**

Richard H. Fish, PhD. (Staff Scientist/Chemist, Lawrence Berkeley National Laboratory). Dr. Fish received a BS in Chemistry from the University of Rhode Island in 1961 and a PhD in organic/organometallic chemistry in 1964. His primary research interest the last 6 years at LBNL has been in the environmental separation sciences field and focused on the synthesis of designer polymer pendant ligands/templated polymers for selective metal ion removal from waste waters. He is the author of over 125 publications, patents, book chapters, and reviews on organic, organometallic, and environmental chemistry topics. Previous support of the imprinted polymer chemistry, FY 1993-FY 1997, by the U. S. Department of Energy, Office of Environmental Management.

George M. Murray, PhD (Staff Scientist/Chemist, John Hopkins University, Applied Physics Laboratory). Dr. Murray received a BS in Chemistry from the University of Tennessee in 1982 and a PhD in Analytical Chemistry in 1988 from the same institution. His primary research interests the last 5 years has been in the templated polymer field and focused on the synthesis of designer templated polymers for selective metal ion sensors and the fabrication of sensor devices, using both optical and electrochemical detection. He is the author of over 50 publications, patents, book chapters, and reviews on environmental and analytical chemistry topics. Imprinted polymer chemistry support, FY 1997-FY 1999, by the U. S. Department of Energy, Office of Environmental Management.

Nigel Quinn PhD, P.E. (Geological Scientist, Lawrence Berkeley National Laboratory) Dr. Quinn received a BSc (Hons) in irrigation engineering and hydrology from the Cranfield Institute of Technology in England, an MS in Agricultural and Civil Engineering from Iowa State University and a PhD in civil and environmental engineering from Cornell University in 1987. His primary research interests have centered on the development of real-time forecasting tools for the San Joaquin River and selenium fate and transport modeling. He is the author of over 50 publications and reports on various aspects of water resources and drainage engineering.

SUBJECT: Grassland Area Farmers Support for CALFED Grant Proposals.

Dear Dr. Fish:

The Grassland Area Farmers have a long history of supporting innovative drainage reduction strategies on the west side of the San Joaquin Valley. As the proponent of the Grassland Bypass Project, the Grassland Area Farmers have invested millions of dollars in the past 3 years to improve monitoring and increase control over subsurface tile drainage leaving the area. Significant reductions in selenium loads contained in these discharges have been necessary to meet the strict selenium load limits imposed by the Project.

The CALFED proposal entitled "Real-Time Sensors for Selenate and Mercuric Ions Utilizing Templated Polymer Technology" is of great interest to the Grassland Area Farmers. The Grassland Area Farmers spend tens of thousands of dollars each year on selenium analyses to monitor discharge within the drainage area to meet monthly selenium load targets. The most troubling aspect of these analyses is the time it takes to obtain a result - often a week or more. A real-time selenium sensor that could provide information to our existing telemetered monitoring system could not only save the Grassland Area Farmers money but also provide more timely information.

Sincerely,

Joseph C. McGahan  
 Drainage Coordinator for Grassland Area Farmers

Subject: Panoche Water District Support for CALFED Grant Proposals

Dear Dr. Fish:

The Panoche Water District has a long history of supporting innovative drainage reduction strategies on the west-side of the San Joaquin Valley. As a participant in the Grassland Bypass Project the water district has invested millions of dollars in the past 3 years to improve monitoring and increase control over subsurface tile drainage leaving the water district. Significant reductions in selenium loads contained in these discharges have been necessary to meet the strict selenium load limits imposed by the Project.

The CALFED proposal entitled "Real Time Sensors for Selenate and Mercuric Ions Utilizing Templated Polymer Technology" is of great interest to the District. The District spends tens of thousands of dollars each year on selenium analysis to monitor individual sumps within the District and to help meet monthly selenium load targets. The most troubling aspect of this analysis is the time it takes to obtain a result - often a week or more. A real-time selenium sensor that could be hooked up to our existing telemetered monitoring system could not only save the District money but also provide more timely information.

Sincerely,

Dennis Falaschi  
General Manager

March 30, 1999.

Ms. Lydia Beiswanger, Chief Deputy  
Merced County Board of Supervisors  
2222 M Street  
Merced, CA 95340.

Dear Ms. Beiswanger:

This letter is to inform you of our intent to submit a proposal to the CALFED Bay-Delta Program entitled "Real-Time Sensors for Selenate and Mercuric Ions Utilizing Templated Polymer Technology". If successful in our application we intend to test this sensor at sites within the Grasslands Drainage Basin and at gauging stations such as Crows Landing along the San Joaquin River.

Agricultural and wetland water districts within the county spend tens of thousands of dollars each year on selenium analysis to monitor supply water and drainage return flows. The most troubling aspect of this analysis is the time it takes to obtain a result -- often a week or more. A real-time selenium sensor that could be hooked up our existing telemetered monitoring system could not only save these water districts money but also provide more timely information.

Likewise, in the both the San Joaquin Valley and Sacramento Valley, mercury associated with sediments from mine sites, mobilized by rainfall-runoff events creates hazards to the riverine ecosystem. A real-time mercury sensor would help to provide quantification and early warning of these hazards.

We anticipate considerable interest in the successful development and deployment of these sensors by water districts and wetland managers in Merced County.

Sincerely,

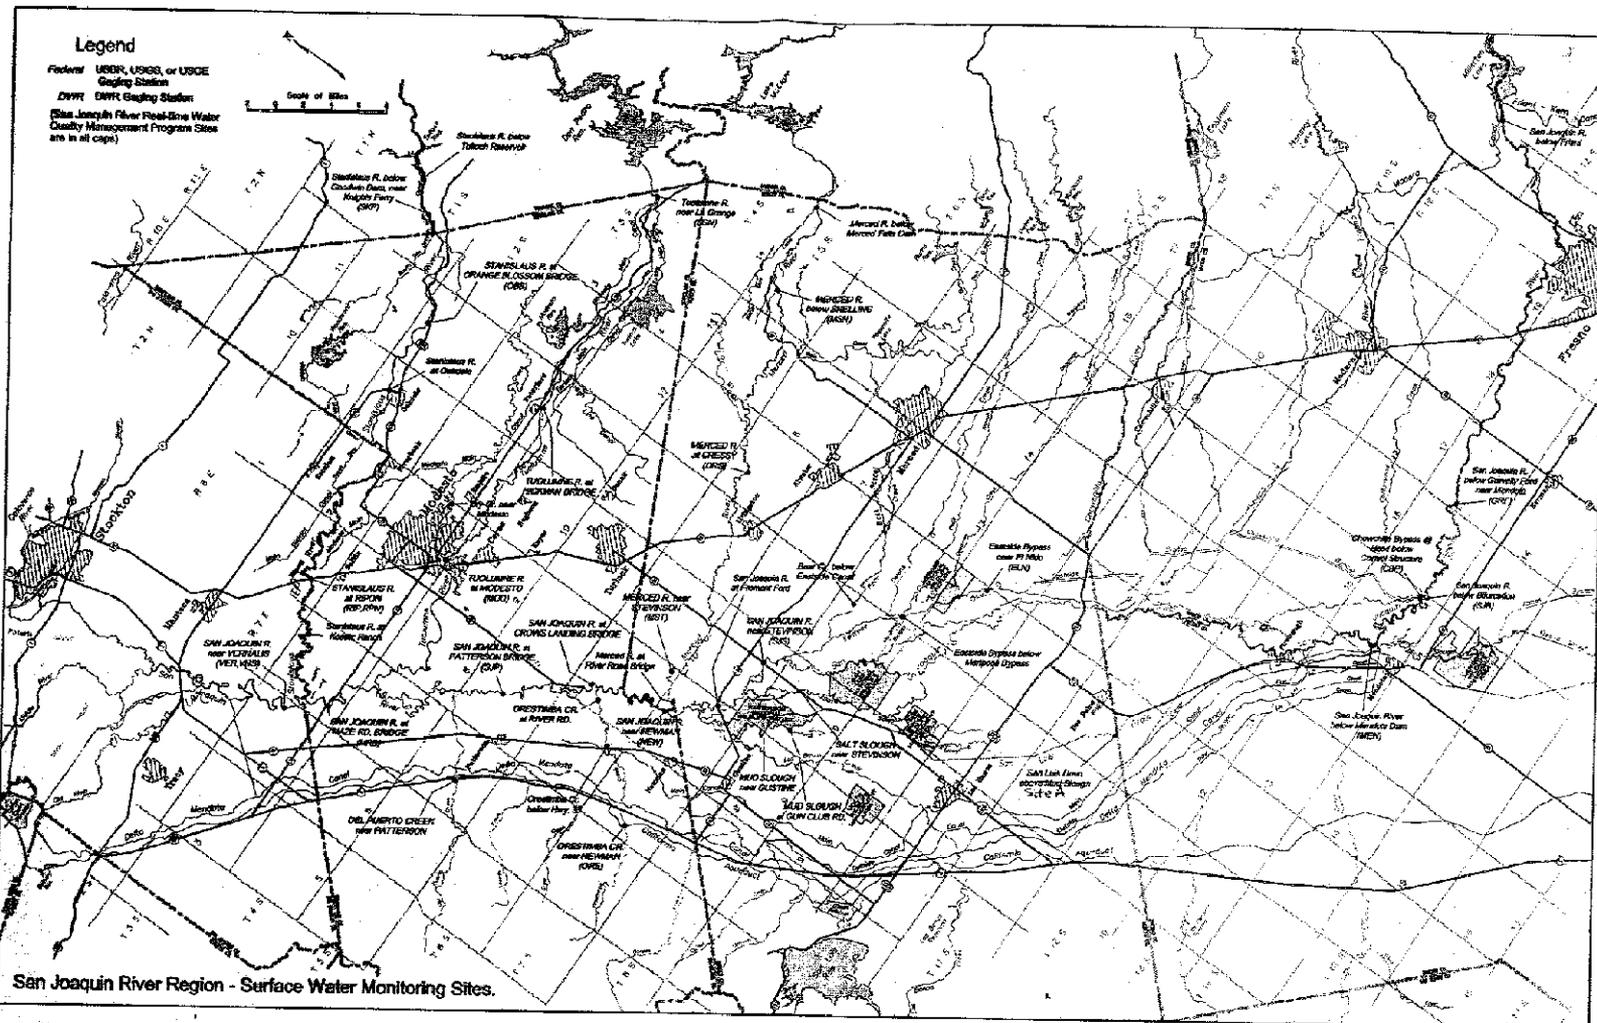

Nigel W.T. Quinn

Geological Scientist
